Key Words : Azodioxide, Thianthrene cation radical, Thermal decay

We recently reported on the thianthrene cation radical perchlorate (Th<sup>+</sup>·ClO<sub>4</sub><sup>-</sup>) induced oxidative decomposition of carbonates (eq 1),<sup>1</sup> carbamates (eq 2),<sup>2</sup> azodicarboxylate (eq 3),<sup>3</sup> dicarbonate (eq 4),<sup>4</sup> peroxides (eq 5),<sup>5</sup> and disulfide (eq 6)<sup>6</sup> where R in equations is *tert*-butyl. In each of these reactions, electron-transfer-mediated C,N, C,O or C,S bond cleavage was found. Substantial bond weakening was shown to accompany the *tert*-butyl cation due to the electron loss from these substrates.

In a continuation of our work on N,N'-dioxoazobis(2methyl-2-propane) (1) in acetonitrile solution at room temperature, C,N and N,O cleavages, followed by addition

of Th<sup>+-</sup>ClO<sub>4</sub><sup>-</sup> to azodioxide, **1**, was found to give thianthrene oxide (ThO) and *N*-*t*-butylacetamide (**3**), with evolution of nitrogen gas. Reactions of Th<sup>+-</sup>ClO<sub>4</sub><sup>-</sup> with anions, such as nitrite and nitrate ions, have been reported,<sup>7</sup> but its reactions with molecules with an abnormal number of bonds have not been documented. This work affords the first example of the addition of a cation radical to formal negatively charged oxygen within a neutral molecule.

Reactions of nitrite and nitrate ions with Th<sup>+·</sup>ClO<sub>4</sub><sup>-</sup> were found to give thianthrene 5-oxide (ThO) quantitatively (Scheme 1). Reactions with <sup>18</sup>O-labeled nitrite and nitrate ions showed that the oxygen in ThO came from the nitrite and nitrate ions respectively.

In the present study, as with the other oxidative decomposition,<sup>1-6</sup> the major products from the reaction of 1 with Th<sup>+</sup>·ClO<sub>4</sub><sup>-</sup> are also characteristic of *tert*-butyl cations, which imply carbocationic chemistry is predominantly observed from a nitrosoalkane dimer. The products obtained were N-tbutylacetamide (3), ThO and N<sub>2</sub> as determined by quantitative GC and GC/MS analyses. N-t-butylacetamide (3) from the tert-butyl cation, which was isolated in a yield of 91%, and ThO (76%) was obtained by oxygen transfer from 1. Without doubt, 3 arose from hydration, during workup, of a Ritter-type intermediate (Me<sub>3</sub>CN=<sup>+</sup>CMe) from the reaction of Me<sub>3</sub>C<sup>+</sup> with the MeCN solvent. Accordingly, all reactions were carried out with a 2:1 stoichiometry of the cation radical and 1. Generally, in the reaction of thianthrene cation radical perchlorate, ThO is obtained as a side product from the hydrolysis of  $Th^+ClO_4^-$  by water, either adventitiously in the solvent or added during workup.<sup>8</sup> However, in this

Scheme 3

reaction, the ThO was the primary product rather than a side product. This result suggests that the oxygen atom in ThO comes entirely form **1**. The formation of ThO, by oxygen transfer from the nucleophiles, as a primary product has been previously reported from the reactions of nitrite and nitrate ions,<sup>7</sup> oximes,<sup>9</sup> cyclic alcohol,<sup>10</sup> and 2,3-dimethyl-2,3-butanediol<sup>11</sup> with Th<sup>+-</sup>ClO<sub>4</sub><sup>-</sup>.

Products obtained from the reaction of  $Th^+ ClO_4^-$  with 1 are shown in Scheme 2, and an explanation for the formation of products is shown in Scheme 3. Azodioxide (1), as in Scheme 3, equilibrates with the 2-methyl-2-nitrosopropane monomer. Because the rate of approach to equilibrium in solution between dimer (1) and monomer is moderately slow (30-60 min) at room temperature and very slow at low temperature,<sup>12</sup> it is possible to prepare and maintain nonequilibrium solutions of the pure dimer (1). Scheme 3 shows that the nucleophile, the negatively charged oxygen of 1, at a high negative charge density, attacks the thianthrene ring, at the sulfur (the 5 position). An intermediate cation radical (2) is formed, which can decompose into a stable product, ThO and 3, with evolution of  $N_2$ . The order of initial bond cleavages either N,O or C,N in the cation radical intermediate, 2, currently remains unknown. The reaction of 1 with Th<sup>+</sup>ClO<sub>4</sub><sup>-</sup> is somewhat unlike the analogous reactions with tert-butyl containing compounds, such as carbonates, carbamates, azodicarboxylate, dicarbonate, peroxides and disulfide. These lead to electron-transfer- mediated oxidative decomposition. In contrast, **1** is first added to  $Th^+ClO_4^-$ , which thereafter decomposes into stable products.

In conclusion, the first example of cation radical-induced thermal decay of stable azodioxide (1) is reported. In the reaction of 1 with a cation radical is quite unlike the analogous reactions described in eq. (1-6). From this reaction, thermal decay rather than electron-transfer-mediated bond cleavage, follows the addition of 1 to the cation radical.
