icaloid characteristically so that they do not require con- certed characters as badly as intramolecular electron transfer process. If there were no character differences between $T_1$ and $S_0$ potentials, electron transfer would be faster than pro- ton transfer in both $T_1$ and $S_0$, admitting that the potential of $Q\dot{N}H^+$, compared with that of $\dot{Q}NH^+$, is expected to be less unstable in $T_1$ than in $S_0$. We attribute the faster re- laxation of the lowest triplet state of HQNH$^+$ species, com- pared with the relaxation of the lowest triplet state of $\dot{Q}N$ species, to the enhanced intersystem crossing rate of the lowest triplet state into the ground state by the vibrations of the O-H and N-H groups that exist exclusively in HQNH$^+$ species. The observation of transient absorption due to ground state $\dot{Q}NH^+$ species indicates that the very weak fluorescence[3] and unobservable ground state absorption of $\dot{Q}NH^+$ species are attributable to the energetically un- favorable potentials rather than to its unfavorable transition[14] between $S_1$ and $S_0$.

In the this short and preliminary report we have tried to reveal that both the reverse electron and proton transfer reac- tions take place in the lowest triplet state potential of 6HQN as well as in its ground state potential. Further ex- tensive studies, the results of which we will report later, on the consecutive electron and proton transfer reactions in $T_1$ of simple 6HQN and its derivative molecular systems would shed light on the currently barely understood roles of the lowest triplet state potential in proton and electron transf- er processes in general.

# Nucleophilic Addition on Nitrogen : Azophilic Addition of Grignard Reagent to 1-Benzyl Tetrazole Substituted Imine
## Sung-eun Yoo* and Young-dae Gong

*Korea Research Institute of Chemical Technology, P.O. Box 107 Yusung, Daejeon, Korea*
*Received February 28, 1997*

Tetrazole have been the primary choice for medicinal chemists as a carboxylic acid isostere because of their sim- ilar acidity $(pK_a \simeq 5)$ to that of the parent carboxylic acid and their stability against metabolism.[1] Recently, particularly in connection with the development of nonpeptidic receptor antagonists of the vasoactive octapeptide angiotensin II, there has been renewed interest in the chemistry of tetra- zoles.[2] In connection with our research programs of design- ing enzyme inhibitors and receptor antagonists, we needed various tetrazole analogs as amino acid isosteres.[3] To this end, we have examined a synthetic methodology based on a nucleophilic addition of the Grignard reagents on imines and herein we would like to report unexpected findings re- garding the regioselectivity in the addition reaction.

There are numerous literature precedents on this type of reactions and it has been known that in most cases the or- ganometallic addition to imines proceeds with a nucleophile attack normally on the carbon atom (carbophilic addition) in- stead of the nitrogen atom (azophilic addition).[4] This type of the reaction, particularly, the reaction of organometallic

**Scheme 3.**

reagents with chiral imines has been successfully used for the preparation of various nitrogen containing natural products and bioactive compounds.

Accordingly our synthetic strategy for the preparation of the aminomethyltetrazole derivatives was planned as depicted in Scheme 1.
The key intermediates **6** was prepared from cinnamonitrile as shown in Scheme 2. Vinyltetrazole **2,** obtained from cinnamonitrile and sodium azide, was protected with a benzyl group. Two benzylated isomers, purified chromatographically, were ozonolyzed to give the corresponding aldehydes **5** which were reacted immediately with optically pure phenethylamine to give tetrazole imines **6.** [5]

We then examined the addition reaction on imine **6** with various Grignard reagents. The addition of methylmagnesium bromide on **6** proceeded smoothly to give exclusively the addition product on the carbon atom **7b** (the carbophilic addition). In contrast the reaction with ethylmagnesium bromide produced **7a** exclusively in which the addition occurs on the nitrogen atom (the azophilic addition). The same azophilic product was also obtained with isopropyl and benzyl magnesium chloride. This result indicates that the reacting site is determined by the type of the Grignard reagent being used. This azophilic addition is quite unusual although there are few examples known for nucleophile attacks on certain electrophilic nitrogen derivatives such as oximes[6] or oxime tosylates.[7] Another known cases for the azophilic addition are when the imine carbon atom is much more hindered than the imine nitrogen atom or when imines were substituted with strong electron withdrawing groups as in the case of fluorenimines and N-alkyltetraphenyl cyclopenta-dienimines.[8] It was also known that the reaction of the α-imino ester with simple Grignard reagents such as ethyl, *i*-propyl and benzyl magnesium halides gave azophilic products.[9,10]

The reason for the azophilic addition is probably due to the anion stabilizing ability of the tetrazole group (Scheme 3).
We also examined the addition reaction of imines **6** with other organometallic nucleophiles such as alkyl lithiums and cuprates. However, we failed to obtain neither of carbophilic or azophilic products indicating that this unusual azophilic addition seems to be unique for the Grignard reagent. It is not clear at this moment why this unusual reaction is unique for the Grignard reagent type nucleophiles. A scope of this reaction and a possible mechanism for the reaction are subjects for our current study.

A typical reaction condition is as follows; To a solution of imine **6** (0.10 g, 0.34 mmole) in dry ethyl ether (8 mL) was added ethylmagnesium bromide (0.25 mL of 3 M solution, 0.75 mmole) at 0 °C. After 30 min., the reaction mixture was quenched with saturated aqueous NH₄Cl solution and then extracted with ethyl acetate. The organic layer was dried over MgSO₄ and concentrated to give the crude product which was purified by prep-TLC (silica gel, hexane/ethyl acetate (3/1)) to give the azophilic addition product **7a** (91.7 mg, 85%).[11]

# Controlling Factors Governing Catalytic Process : Asymmetric Allylation Reaction Promoted by BINOL-Zr(IV) Catalyst with Synergetic Reagent

## Chan-Mo Yu*, Ha-Soon Choi, Won-Hyuk Jung, Hyuk-Jun Kim, and Jeon-Koo Lee

*Department of Chemistry, Sung Kyun Kwan University Suwon 440-746, Korea*
*Received February 28, 1997*

As one of fundamental asymmetric bond forming reactions, allyl transfer reactions from chiral reagents to the carbonyl functionality in forming enantiomerically rich homoallylic alcohols attract considerable attention from the synthetic community because the resulting products serve as chiral building block for multistep synthesis.[1] The exceptional power of the allyllation reaction has been enhanced by newly developed enantioselective versions, especially chiral Lewis acid catalysed allyl transfer reactions.[2] The development of synthetic methods for achieving absolute stereoselection by the utilization of chiral catalysts increasingly requires precise control of the reaction pathway based on mechanistic behavior.[3] Recently, we demonstrated that the utilization of molecular accelerator for the catalytic asymmetric allylation reaction promoted by BINOL-Ti(IV) complex **1** resulted in not only significantly increasing reaction rate but also reducing dosage of chiral catalyst.[4] Described herein is an extension of the conception concerning molecular accelerating strategy to find new catalytic systems and to realize useful and practical asymmetric synthesis, There have been quite limited reports which appeared with chiral Zr species for the catalytic asymmetric synthesis, especially allylic transfer reaction.[5] In the present research, two major progress have been made in this field

for the enantioselective synthesis of homoallylic alcohols: (1) the system employing BINOL-Zr(IV) catalyst with an accelerator exhibited dramatical increasing of catalytic capability (up to 5 mol %); (2) reduced side reaction significantly.

(S)-BINOL-Zr(IV) complex **2** was prepared from the reaction of (S)-BINOL with Zr(O- *i*- Pr)₄ in the presence of activated 4 A molecular sieves. Treatment of **3** (R=CH₂CH₂Ph) with **4** in the presence of chiral catalyst **2** (5 mol %) in CH₂Cl₂ at − 20 °C for 24 h afforded product **5** (R=CH₂CH₂Ph) in 41% yield with 87% ee. We have subsequently observed that synergetic reagents can also be employed for this purpose. After surveying a series of alkylthioboranes and alkylthiosilanes for the allylation promoted by chiral catalyst **2,** several key findings emerged: (1) *i* -PrSBEt₂[6] was generally superior to other reagents including *i* -PrSSiMe₃; (2) a 1 : 1 mixture of BINOL/Zr(O- *i*- Pr)₄ complex was proved to be most effective; (3) the new system exhibited sig-
