Key Words: Angelica dahurica, Umbelliferae, Furanocoumarin, Septic shock

Studies to find preventive agents against sepsis have been reported. ^{1,2} In our previous studies, we have screened more than one hundred of Korean medicinal plants based on *in vivo* sepsis model induced by LPS/D-galactosamine (GalN). *Angelica dahurica* Benth. *et* Hook. (Umbelliferae) was selected as one of the active plants. The roots of *A. dahurica* have been used for the treatment of colds, headaches and toothache in Korean traditional medicine. ³ Some coumarins and furanocoumarins have been reported from this plant. ³⁻⁹ Two new furanocoumarins (1 and 2) were isolated from the *n*-BuOH extract of the roots of *A. dahurica*. The structure elucidation and biological activity of the compounds are described herein.

The MeOH extract of the roots of A. dahurica was partitioned between H_2O and hexane, and the resulting H_2O layer was extracted with EtOAc and n-BuOH, respectively. The n-BuOH extract was chromatographed on Silica-gel column. The two major fractions were separately rechromatographed on a reverse-phase column, which afforded compounds $\bf 1$ and $\bf 2$.

Compound **1** has the molecular formula $C_{21}H_{24}O_7$ as determined by HRFABMS, ¹³C-NMR, and DEPT spectral data. ¹H- and ¹³C-NMR data of **1** were similar to those of the reported psoralen from *Angelica officinalis*, which has the same furanocoumarin backbone as **1** but has two 2-hydroxy-isopentyl groups substituted at C-5 and C-8 position. ¹⁰ The

Figure 1. Structures of compounds 1 and 2.

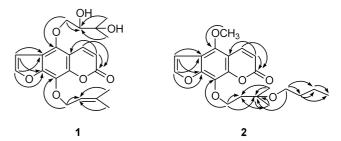

Figure 2. Selective HMBC correlations for compound **1** and **2**.

connectivity among carbons of 1 was determined mainly by analysis of the HMBC spectrum of 1 (Figure 2). Key evidences from ¹H- and ¹³C-NMR, DEPT, ¹H, ¹H- COSY, HMQC and HMBC spectral data were as follows. In the ¹H-NMR spectrum of 1, two doublet signals (1H, J = 9.9 Hz) at δ 8.36 and 6.25 were assigned as the protons of pyrone ring. Two doublet signals (1H, J = 2.4 Hz) at δ 7.90 and 7.26 were assigned as the protons of furan ring.9 The 1H-NMR spectrum of 1 showed the presence of a 5,8-disubstitued furanocoumarin moiety, a 2,3-dihydroxy-3-methylbutyloxy moiety [δ 4.74 (1H, dd, J = 9.9, 2.4 Hz), 4.31 (1H, dd, J = 9.9, 8.4 Hz), 3.87 (1H, dd, J = 8.4, 2.2 Hz), 1.26 (3H, s), 1.23 (3H, s)], and a 3-methylbut-2-envloxy moiety [δ 5.55 (1H, t, J = 7.2 Hz), 4.82 (1H, d, J = 7.2 Hz), 1.70 (3H, s), 1.66 (3H, s)]. In the HMBC spectrum of 1, the location of 3methylbut-2-envloxy moiety was established by a longrange correlation between C-8 with H-1", and the position of a 2',3'-dihydroxy-3'-methylbutyloxy group was determined by both a long-range correlation between C-5 with H-1' and a positive NOE effect between H-9 and H-1' in the 1D-NOE difference spectrum of 1. 11,12 The absolute stereochemistry of the chiral center in 1 was determined by using Moshers ester based on the differences between the 1H-NMR chemical shifts of (S)- and (R)-MTPA ester derivatives. 13-15 ¹H-NMR data were assigned based on the ¹H-¹H COSY spectra of $\mathbf{1}_S$ and $\mathbf{1}_R$ (Table 1). For $\mathbf{1}$, the positive value of $\Delta \delta_{\rm H} (\delta_{\rm S} - \delta_{\rm R})$ at H-1' and the positive value of $\Delta \delta_{\rm H} (\delta_{\rm S} - \delta_{\rm R})$ at H-4' and H-5' suggested an R configuration at C-2'.

Compound **2** had the molecular formula $C_{21}H_{26}O_7$ as determined by HRFABMS, ¹³C-NMR, and DEPT spectral data. ¹H- and ¹³C-NMR spectra showed not only signals very similar to those of byakangelicin, ¹⁶ but also signals due to one butoxyl moiety. The ¹³C-NMR signal of C-3' at δ 77.2,

Table 2. Effect of the compound **1** on LPS/D-GalN-induced lethality in mice

	Control	10 (mg/kg)	30 (mg/kg)	100 (mg/kg)
Compound 1	1/5 ^a	1/5	2/5	3/5
Dexamethasone ^b	1/5	4/5	ND^c	ND

"Number of live mice/number of total mice; bpositive control; not determined. Mice were injected i.p. with various doses of compound 1 or vehicle 30 min before injection of LPS/D-GalN. Survival rate was observed once daily for up to 3 days.

which is 5.7 ppm lower than that of free byakagelicin, suggested that butoxyl moiety is linked to C-3' position of $2.^{17}$ The location of butoxyl moiety was established by the HMBC long-range correlation between C-3' and H-6' (Figure 2), and positive NOE effects from H-6' to H-2', H-4', and H-5' in the 1D-NOE difference spectrum and comparison of the NMR spectral data with those of 9-(2-hydroxy-3-methoxy-3-methylbutoxy)-bergapten. To determine the absolute configuration of the hydroxyl group at C-2', Moshers esters (2_R and 2_S) of 2 were prepared, and 1 H-NMR data were also assigned based on the 1 H, 1 H-COSY spectra (Table 1). For 2, the positive value of $\Delta\delta_H$ (δ_S - δ_R) at H-1' and the negative value of $\Delta\delta_H$ (δ_S - δ_R) at H-4' and H-5' suggested an R configuration at C-2'.

Of two purified compounds, only 1 showed protective effect against lethality induced by LPS/D-GalN (Table 2). Pretreatments of mice with 1 at doses of 10, 30, and 100 mg/kg increased survival rates to 20%, 40%, and 60%, respectively, while the control showed 20% increase of survival rate. However, the protective effect of 1 was lower than that of dexamethasone.

Experimental Section

General Experimental Procedures. Optical rotations were measured using a JASCO DIP-1000 digital polarimeter. IR spectra were recorded on a JASCO FT-IR 300E spectrophotometer, and UV spectra were recorded on a JASCO V-550 spectrophotometer. NMR spectra were recorded on Bruker 250 MHz (DMX 250) spectrometer using Bruker's standard pulse program. Samples were dissolved in either CD₃OD or acetone- d_6 , and chemical shifts were reported in δ (ppm) downfield from TMS. The FABMS spectra were measured by VG TRIO 2A mass spectrometer. Silica-gel 60 (70-230 and 270-400 mesh, Merck) and Lichroprep RP-18 gel (40-63 mm, Merck) were used for column chromatography. TLC plates (Silica-gel 60 F₂₅₄ and RP-18 F₂₅₄) were

purchased from EM Scientific. Spots were detected under UV radiation and by spraying with 10% H₂SO₄, followed by heating. All other chemicals and solvents were analytical grade and used without further purification.

Plant Material. Dried *A. dahurica* roots were purchased in November 1997 from a traditional medicine market "Yakryong-si" in Daegu, and the material was confirmed taxonomically by Professor Gi-Hwan Bae, of Chungnam National University in Taejeon, Republic of Korea. A voucher specimen (YNS-97-01) has been preserved at the College of Pharmacy, Yeungnam University.

Isolation. The dried roots of A. dahurica (10 kg) were extracted twice with 70% MeOH (20 L) under reflux for 12 h. The MeOH solution was evaporated to dryness (3 kg) and the residue was partitioned between H2O (1 L) and hexane $(3 \times 1 \text{ L})$. The resulting H₂O layer was extracted with EtOAc $(3 \times 1 \text{ L})$ and *n*-BuOH $(3 \times 1 \text{ L})$ successively. The *n*-BuOH extract (110 g) was chromatographed on a silica gel column $(230-400 \text{ mesh}, 60 \times 9 \text{ cm}) \text{ with } CH_2Cl_2\text{-MeOH-H}_2O (100 : 100 \times 9 \text{ cm})$ 1:0.1, 50:1:0.1, 30:1:0.1, 20:1:0.1, 10:1:0.1, 9:2:0.1, 9:4:0.1, 3:8:0.1, 100% MeOH) in a stepwise gradient mode. The fractions (500 mL in each flask) were grouped and combined on the basis of silica-gel TLC and 36 subfractions (F1-F36) were obtained. The subfraction F2 (450 mg) from the column was further purified on a reverse-phase column (75 × 2.6 cm, LiChroprep RP-18) with MeOH-H₂O (gradient from 1:9 to 2:8), affording **1** (34.6 mg). The subfraction F7 (650 mg) was further rechromatographed on a reversedphase column (70 × 3.0 cm, LiChroprep RP-18) with MeOH-H₂O (gradient from 2:8 to 100% MeOH) to give 2 (25.6

Preparation of Mosher's Esters. A previously described method was used. 13-15 To each 1 mg of compounds 1 and 2 in 0.5 mL of CH₂Cl₂ were added sequentially 0.2 mL of pyridine, 0.5 mg of 4-(dimethylamino)pyridine, and 12.5 mg of (R)-(-)- α -methoxy- α -(trifluoromethyl)phenylacetyl [(R)-MTPA] chloride, separately. The mixture was left at room temperature overnight and purified over a microcolumn (0.6 × 6 cm) of silica gel (230-400 mesh) eluted with 3-4 mL of hexane-CH₂Cl₂ (1 : 2). The elute was dried, CH₂Cl₂ (5 mL) was added, and the CH2Cl2 was washed using 1% NaHCO3 $(2 \times 5 \text{ mL})$ and H₂O $(2 \times 5 \text{ mL})$. The washed elute was dried in vacuo to give the S-Mosher esters $(\mathbf{1}_S \text{ and } \mathbf{2}_S)$ of compounds 1 and 2, respectively. Using (S)-MTPA chloride afforded the R-Mosher esters $(\mathbf{1}_R \text{ and } \mathbf{2}_R)$ of compounds $\mathbf{1}$ and 2, respectively. Their ¹H-NMR chemical shifts are given in Table 1.

Animals and LPS/D-GalN-Induced Lethality. Male ICR mice weighing 23-28 g were housed 5 per cage in a room maintained at 22 ± 1 °C with an alternating 12 hours light-dark cycle. Food and water were available *ad libitum*. LPS (*Escherichia coli* 055:B5, Sigma, USA) was dissolved in phosphate-buffer saline (PBS, pH 7.2) at 1 μ g/ μ L and stored at -80 °C until use. D-GalN (ICN, USA) was dissolved in PBS at 0.16 g/mL and added to 7.2 μ L of LPS solution. Each mouse received LPS/D-GalN (LPS 36 μ g/kg, D-GalN 0.8 g/kg) intra-peritoneally at volume of 1 mL/100 g of body weight. Compounds 1 and 2 were dissolved in 10% DMSO and injected to mice by i.p. administration

before LPS/D-GalN injection. Survival rate was observed once daily for up to 3 days.
