Recently, Basavaiah and Rao reported the synthesis of substituted  $\gamma$ -lactams by the reductive cyclization of  $\gamma$ -nitroesters, which were prepared from the reaction of the acetates of Baylis-Hillman adducts and nitro compounds.<sup>1</sup>  $\gamma$ -Nitrocarbonyl compounds could be transformed into cyclic nitrones or pyrroline derivatives depending upon the reduction conditions and the nature of the carbonyl groups.<sup>1,2</sup> Various reduction conditions have been used for the reductive cyclization of  $\gamma$ -nitrocarbonyl compounds including Fe/AcOH,<sup>1</sup> Zn/NH<sub>4</sub>Cl,<sup>2a-d</sup> and catalytic hydrogenation.<sup>2e,2f</sup>

Suitably substituted pyrrolines<sup>3</sup> or cyclic nitronone derivatives<sup>4</sup> have been prepared and used as important synthetic intermediates.<sup>1-4</sup> During the investigation on the chemical transformations of Baylis-Hillman adducts,<sup>5</sup> we intended to examine the reductive cyclization of  $\gamma$ -nitroketone derivatives **2** derived from the acetates of Baylis-Hillman adducts as shown in Scheme 1. The starting materials **2a-e** were easily prepared by the S<sub>N</sub>2' reaction of primary nitroalkanes and the acetates of the Baylis-Hillman adducts according to the previous method.<sup>1,5</sup> We tried the reductive cyclization of **2a** under various conditions and the results are summarized in Table 1 (entries 1-3). As shown in Table 1, we obtained mixtures of 4-benzylidene-2,5-dimethyl-3,4-dihydro-2H-pyrrole (**5a**) and cyclic nitronone derivative **6a** in variable yields. The use of Fe/AcOH gave the pyrroline derivative **5a** as the major product under refluxing conditions (entry 1). Whereas, we obtained the cyclic nitronone derivative **6a** as the major product when we use Zn/NH<sub>4</sub>Cl at low temperature (entry 3). The use of Fe/AcOH (entry 2) at lower temperature and Zn/NH<sub>4</sub>Cl at room temperature (not shown) showed diminished selectivity. In spite of our extensive efforts we failed to obtain higher selectivity. Similarly, we synthesized **5b-e** and **6b-e** from the reaction of **2b-e** under

Fe/AcOH/reflux conditions and the results are summarized in Table 1.

For the substrates **2b-d**, pyrroline derivatives **5b-d** were isolated as the major products. However, nitronone **6e** was obtained as the major product in the case of dimethyl-substituted starting material **2e** (entry 7). Structure identification of the synthesized products was carried out by their <sup>1</sup>H and <sup>13</sup>C NMR, IR, mass, and chemical transformations (vide infra). The stereochemistry of the double bond of **5a** and **6a** was confirmed as *E* based on NOE experiments (shown in Table 1).<sup>1,5</sup> The mechanism for the formation of **5** and **6** was proposed as in Scheme 2 with **5a** and **6a** as the representative examples. Reduction of the nitro group into amino group to form **3a** and the following condensation gave **5a**. Partial reduction to hydroxylamine derivative **4a** and the following cyclization and dehydration afforded **6a**.

In order to verify the usefulness of the prepared pyrroline compounds **5**, we examined the Michael addition reaction of the acidic methyl group at the 5-position of **5a** toward acrylonitrile or methyl acrylate (Scheme 3).<sup>6</sup> The reaction of pyrroline **5a** and acrylonitrile in THF in the presence of catalytic amounts of base (DBU or NaOMe) produced intractable mixtures of products. Fortunately, we could obtain **8a** in moderate yield (59%) by refluxing **5a** in acrylonitrile without any base and solvent for long time (60 h). First introduction of acrylonitrile to the methyl group of **5a** produced the corresponding mono adduct (**1**), which reacted once more with acrylonitrile to produce **8a**. But, the third introduction of acrylonitrile to **8a** did not occur presumably due to the steric hindrance. The Michael addition reaction was thought to occur *via* the imine-enamine tautomerization as shown.<sup>7</sup> Similarly, we obtained **7a** from the reaction of **5a** and methyl acrylate in 58% yield. compound **7a** could be transformed to bicyclic lactam derivative **9a** in refluxing toluene in the presence of acetic acid in 48% yield.<sup>8,9</sup> We also tried the reactions of **5e** and **5c** and obtained the corresponding tetrahydroindolizinone derivatives **9b** and **9c** via the corresponding intermediates

**7b** and **7c** although the yields were relatively low (Schemes 4 and 5).

In summary, we disclosed the reductive cyclization of  $\gamma$ -nitrocarbonyl compounds derived from Baylis-Hillman adducts into cyclic nitron and pyrroline derivatives.

Selective double Michael addition reaction of the pyrroline compounds was observed for the first time. Further studies on the synthesis of bicyclic lactam derivatives and transformation into natural alkaloid derivatives are underway.<sup>9</sup>
