**Key Words:** *N*-{6-Methyl-2-pyridyl)methyl}-(*S*)-1-phenylethylamine, Chiral Zn(II) complex, PLA, X-ray structure

Poly(lactic acid) or polylactide (PLA) is a biodegradable synthetic polymer.<sup>1</sup> A typical degradation time is months to years for L-PLA and weeks to months for *rac*-PLA.<sup>2</sup> This time scale is several orders of magnitude shorter than that of petroleum-based polymers, which makes it possible to compost PLA waste just into soil amendments. In addition to this green benefit, PLA's raw material is from annually renewable resources such as corn and sugar beets or even from the food wastes. Moreover, basic physical properties of PLA that include narrow MWD, low haze, high mechanical strength, high gas permeability and easy processibility are acceptable enough to utilize this material in many applications such as fiber, film, and blow molding.<sup>3</sup> Due to these merits not to mention skyrocketing natural oil price, PLA have emerged as an environmentally friendly plastic materials that can replace many petroleum-based ones.

It has been known that the catalyst-initiated ring-opening polymerization reaction of purified lactide is advantageous over the condensation reaction of lactic acid in terms of a higher polymerization rate, a higher MW, and a better conversion. Among many different kinds of metal species for the polymerization catalysts, relatively non hazardous magnesium and zinc,<sup>4-13</sup> or aluminum<sup>4,10,14-31</sup> have attracted more attention than highly toxic tin,<sup>6,32-41</sup> lead and bismuth,<sup>42</sup> or lanthanides<sup>43-48</sup> because the major application fields of PLA are biomedical<sup>49</sup> and food packaging<sup>5</sup> and even ppm level catalyst residues are potentially harmful for these application. Along this line, we attempted to prepare PLA with the newly synthesized zinc complex ligated by the chiral *N*-{6-methyl-2-pyridyl)methyl}-(*S*)-1-phenylethylamine (MPMA) ligand. Instead of a direct complexation reaction between MPMA and dialkylzinc to prepare an active catalyst species as in our previous work,<sup>50</sup> we first synthesized air and moisture stable (MPMA)ZnCl<sub>2</sub> complex and generated the active catalyst species by treating it with benzylmagnesium chloride (BnMgCl) *in situ*. Herein, we report the synthesis of MPMA ligand as well as its ZnCl<sub>2</sub> complex, the X-ray crystal structural characterization of the complex, and the polymerization results of *rac*-lactide with *in situ* generated (MPMA)ZnBn<sub>2</sub>.

## Experimental Section

**Materials.** All manipulations were carried out under nitrogen prepurified by passage through an O<sub>2</sub> scrubbing tower (Schweizerhall R3-11 catalyst) and a drying tower (Linde 3-Å

molecular sieves) unless otherwise noted. Standard Schlenk and drybox techniques were employed to manipulate air sensitive materials. All solvents were purchased from Duksan Chemical Co. (reagent grade). Tetrahydrofuran (THF) was dried over Na/benzophenone ketyl, while CH<sub>2</sub>Cl<sub>2</sub> was dried over CaH<sub>2</sub>; these solvents were subsequently distilled from these reagents under nitrogen prior to use. Methyl alcohol was used as received. The *rac*-lactide was purchased from Aldrich and was sublimed prior to use. 6-Methyl-2-pyridine carboxaldehyde, (*S*)-(-)- $\alpha$ -methylbenzylamine, sodium borohydride, zinc chloride and benzylmagnesium chloride (2 M in THF) were purchased from Aldrich and used as received.

**Instrumentation.** <sup>1</sup>H-NMR spectra were recorded on a Bruker advance digital 400-NMR Spectrometer at ambient temperature and chemical shifts were referenced to tetramethylsilane as internal standard and are reported in ppm. All coupling constants are reported in Hertz. Elemental analyses were determined using EA 1108-Elemental Analyzer at the Chemical Analysis Laboratory of the Center for Scientific Instruments of Kyungpook National University. Gel permeation chromatography (GPC) analyses were carried out on a Waters Alliance GPCV2000, equipped with differential refractive index detectors. The GPC columns were eluted with tetrahydrofuran with 1 mL/min rate at 25 °C and were calibrated with monodisperse polystyrene standards.

***N*-{6-Methyl-2-pyridyl)methyl}-(*S*)-1-phenylethylamine (MPMA).** Reported method for MPMA was modified as followings.<sup>51</sup> In the first step, 6-methyl-2-pyridine carboxaldehyde (1.05 g, 8.5mmol) and (*S*)-(-)- $\alpha$ -methylbenzylamine (1.1 mL, 8.5mmol) were mixed in 15mL methanol and were stirred overnight at ambient temperature. NaBH<sub>4</sub> (0.33g, 8.8mmol) was added slowly in the second step and the reaction mixture was stirred for 3 hours. After removing methanol by rotary evaporation, the residue was partitioned in CH<sub>2</sub>Cl<sub>2</sub> (50 mL) and H<sub>2</sub>O (25 mL). The organic layer was washed with H<sub>2</sub>O (2 × 25 mL), dried over CaCl<sub>2</sub>, filtered, and evaporated. MPMA was obtained as yellowish oil; isolated yield = 1.86g (8.2 mmol, 96%). <sup>1</sup>H-NMR (400 MHz, CDCl<sub>3</sub>);  $\delta$  7.39 (t, 1H, *J* = 7.52 Hz, ArH), 7.30-7.22 (m, 4H, ArH), 7.19-7.14 (m, 1H, ArH), 6.90 (t, 2H, *J* = 6.52 Hz, ArH), 3.74 (q, *J* = 6.56 Hz, 1H, CH), 3.59 (s, 2H, CH<sub>2</sub>), 2.45 (s, 3H, PyCH<sub>3</sub>), 2.19 (br, s, 1H, NH), 1.30 (d, *J* = 6.56 Hz, 3H, CH<sub>3</sub>).

**(MPMA)ZnCl<sub>2</sub>.** A 100 mL, one-necked round-bottomed flask was charged with MPMA (1.02g, 4.5 mmol), ZnCl<sub>2</sub> (0.62g, 4.5 mmol) and THF (15 mL). The mixture was stirred at am-

bient temperature for 3 days and then the solvent was removed under reduced pressure. The residual solids were dissolved in  $\text{CH}_2\text{Cl}_2$  and filtered through filter paper. The filtrate was evaporated *in vacuo* to afford white solids. Recrystallization of the crude product from a solvent pair of  $\text{CH}_2\text{Cl}_2$ /Hexane gave white crystals; isolated yield = 1.42 g (3.9 mmol, 87% based on 4.5 mmol of MPMA).  $^1\text{H-NMR}$  (400 MHz,  $\text{CD}_3\text{CN}$ );  $\delta$  7.89 (t, 1H,  $J = 7.89$  Hz, ArH), 7.48-7.40 (m, 6H, ArH), 7.16 (d,  $J = 7.79$  Hz, 1H, ArH), 4.15 (m, 2H, NH & CH), 3.77 (m, 2H,  $\text{CH}_2$ ), 2.78 (s, 3H,  $\text{PyCH}_3$ ), 1.70 (d,  $J = 3.24$  Hz,  $\text{CH}_3$ ). Elemental Analysis  $\text{C}_{15}\text{H}_{18}\text{Cl}_2\text{N}_2\text{Zn}$ : Calc: C 49.68; H 5.00; N, 7.73. Found: C 49.79; H 5.01; N 7.74%.

**Polymerization with *in situ* generated (MPMA)ZnBn<sub>2</sub>.** A 100 mL Schlenk tube previously dried at 150 °C and cooled under nitrogen, was charged with (MPMA)ZnCl<sub>2</sub> (361 mg, 1.0 mmol) and dried THF (9 mL). After cooling the solution to -78 °C, 1.0 mL of BnMgCl (2.0 M in THF) was added drop wise into the stirred solution. The white suspension became clear immediately. The mixture was allowed to warm to room temperature. After being stirred overnight at ambient temperature, the resulting catalyst solution was used for the polymerization reaction. The general procedure for the polymerization reaction was as follows. A 100 mL of Schlenk tube previously dried at 150 °C and cooled under nitrogen was charged with *rac*-Lactide (1.44 g, 10.0 mmol) in the glove box. Dried THF (10 mL) was transferred to the reaction vessel via cannula. The reaction was initiated by adding the catalyst solution (2 mL, 1 mL and 0.5 mL for the  $[\text{M}]/[\text{cat}] = 50, 100$  and 200, respectively.) with syringe. The reaction mixture was stirred at ambient temperature for 2 hours. The reaction was quenched by adding 1 mL of water and partitioned with  $\text{CH}_2\text{Cl}_2$  (100 mL) and 0.05 N HCl; the organic layer was washed with 0.05 N HCl ( $2 \times 25$  mL) and  $\text{H}_2\text{O}$  ( $1 \times 50$  mL), following which it was dried over  $\text{CaCl}_2$ , filtered, and evaporated, giving a white gum. Unreacted monomeric lactide was removed by sublimation. The resulting gummy product was dissolved in small amount of  $\text{CH}_2\text{Cl}_2$  (~5 mL), filtered, and quickly dried *in vacuo*. White crumble solids was obtained. Isolated yield; 1.4 g, 97% based on *rac*-Lactide.  $^1\text{H NMR}$ (300

MHz,  $\text{CDCl}_3$ ):  $\delta$  5.19-5.04 (m, 1H), 1.52-1.47 (m, 3H)

**X-ray crystallographic analysis for (MPMA)ZnCl<sub>2</sub>.** An X-ray quality single crystal was mounted in a thin-walled glass capillary on an Enraf-Nonius CAD-4 diffractometer with Mo-K $\alpha$  radiation ( $\lambda = 0.71073$  Å). Unit cell parameters were determined by least-squares analysis of 25 reflections ( $10^\circ < \theta < 13^\circ$ ). Intensity data were collected with  $\theta$  range of 1.88-24.97° in  $\omega/2\theta$  scan mode. Three standard reflections were monitored every 1 hr during data collection. The data were corrected for Lorentz-polarization effects and decay. Empirical absorption corrections with  $\Psi$ -scans were applied to the data. The structure was solved by using Patterson method and refined by full-matrix least-squares techniques on  $F^2$  using SHELX-97 and SHELX-97 program packages.<sup>52,53</sup> All non-hydrogen atoms were refined anisotropically and all hydrogen atoms were constrained by using riding model. The final cycle of the refinement converged with  $R_1 = 0.025$  and  $wR_2 = 0.067$ . Crystal data, details of the data collection, and refinement parameters are listed in Table 1. Selected bond distances and angles are presented in Table 2.

## Results and Discussion

The MPMA ligand was readily synthesized from the 2-steps one-pot reaction comprising the condensation reaction between 6-methylpyridine-2-carboxyaldehyde and chiral (S)-1-phenylethylamine and the following reduction of the corresponding Schiff base imine intermediate. For the reduction reaction of the intermediate imine compound for the conversion of the imine intermediate to the amine analogue, we used  $\text{NaBH}_4$  as a reducing agent. This approach was quite efficient giving rise to 96% of overall yield, which is much higher than that conducted separately (Scheme 1).<sup>51</sup>

The complexation reaction between MPMA ligand and  $\text{ZnCl}_2$  was followed by the method reported previously.<sup>50</sup> Since both MPMA and  $\text{ZnCl}_2$  are freely soluble in THF while (MPMA)ZnCl<sub>2</sub> is not, the desired product was easily isolated by filtration. It should be noted that the early studies regarding (2-aminomethylpyridine)<sub>n</sub>ZnCl<sub>2</sub> complexes ( $n = 1, 2,$  and 3) revealed that the ligand-to-metal ratio of the product is critically dependent on the ligand-to-metal ratio of reactants used in the preparation stage. Given the fact that MPMA ligand has a similar skeleton with 2-aminomethylpyridine, we were careful about the controlling the stoichiometry between MPMA and  $\text{ZnCl}_2$  to avoid possible contamination of bis- or tris-ligated side products. Although we have not carried out a kinetic control, the obtained product was solely (MPMA)ZnCl<sub>2</sub>, which was confirmed by  $^1\text{H NMR}$ , elemental analysis, and X-ray crystal structural determination.

A single crystal suitable for the X-ray crystallography was obtained by a diffusional crystallization of (MPMA)ZnCl<sub>2</sub> in

$\text{CH}_2\text{Cl}_2$  and hexane. An ORTEP drawing of the complex is shown in Figure 1 with the atomic labeling. Selected bond distances and angles are listed in Table 1. The geometry of the complex is a distorted tetrahedron comprising zinc metal as a center linked with two N atoms of MPMA ligand in a bidentate manner along with two chloride ions. The angle between  $\text{Cl}(1)\text{-Zn-Cl}(2)$  and  $\text{N}(1)\text{-Zn-N}(2)$  planes are  $89.76(7)^\circ$ . Two binding sites of the tetrahedron are occupied by large chloride ions while the other two are chelated by a bidentate ligand, which give rise to much smaller N-Zn-N bite angle ( $83.17^\circ$ ) than Cl-Zn-Cl angle ( $114.99^\circ$ ). This is a common structural feature in  $\text{L}_2\text{ZnX}_2$  type complex where  $\text{L}_2$  is a nitrogen donor bidentate ligand and X is a halogen ion. For example, a similar complex (propylideneaminomethylpyridine)  $\text{ZnCl}_2$  reported by Westerhausen *et al.*<sup>54</sup> exhibit  $82.2^\circ$  and  $115.52^\circ$  of N-Zn-N and Cl-Zn-Cl angles. On the other hand, bond distances for Zn-N(1) and Zn-N(2) of (MPMA)  $\text{ZnCl}_2$  are 2.049(3) and 2.082(3) Å, respectively. Slightly longer distance of Zn-N(2) bond relative to that of Zn-N(1) might be due to the  $\text{sp}^3$  character of N(2) atom in contrast to  $\text{sp}^2$  one of N(1). It is interesting to note that the bond distance of Zn-Cl(2) is significantly longer (+0.036 Å) than that of Zn-Cl(1). In case of

**Scheme 1.** Synthesis of (MPMA)  $\text{ZnCl}_2$  and (MPMA)  $\text{ZnBn}_2$ .

**Figure 1.** ORTEP drawing of (MPMA)  $\text{ZnCl}_2$  with the numbering scheme and 40% probability ellipsoids.

(propylideneaminomethylpyridine)  $\text{ZnCl}_2$ , for example, two Zn-Cl bond distances were 2.050 and 2.054 Å.<sup>55</sup> (*N,N,N'*-trimethylethylenediamine)  $\text{ZnCl}_2$  complex exhibited 2.207 and 2.212 Å of Zn-Cl bond distances.<sup>56</sup> Considering the fact that the difference of two Zn-Cl bond distances of both (propylideneaminomethylpyridine)  $\text{ZnCl}_2$  and (*N,N,N'*-trimethylethylenediamine)  $\text{ZnCl}_2$  were only 0.004 and 0.005 Å, 0.036 Å difference between two Zn-Cl bond distances in our result is exceptional. It is not likely that this phenomenon is derived from the effect of two nitrogen atoms of different hybridization character because two Zn-Br bond distances in (aminomethylpyridine)  $\text{ZnBr}_2$  complex, for example, in which one nitrogen has  $\text{sp}^3$  character and another has  $\text{sp}^2$  one similar to (MPMA)  $\text{ZnCl}_2$ , are very similar each other (2.360 and 2.357 Å).

Between two nitrogen atoms in MPMA ligand, only N(2) atom is able to become a chiral center when it is coordinated to the zinc metal. The inherent chirality located on C(8) atom should remain unchanged after coordination. The resulting structure determined by X-ray crystallography revealed that only one stereogenic species was generated by the complexation reaction, giving rise to enantiomerically pure *R* configurations for N(2) atoms.

Polymerization reaction of *rac*-lactide was carried out with *in situ* prepared Zn catalyst, (MPMA)  $\text{ZnBn}_2$ , which was prepared by treating two equivalent of  $\text{BnMgCl}$  to (MPMA)  $\text{ZnCl}_2$  in THF solvent. We have run the polymerization reaction in three different [monomer]/[catalyst] ratios. The polymerization results were summarized in Table 2. When the [monomer]/[catalyst] ratio ( $R_{\text{monomer/cat}}$ ) is 50, the polymerization reaction was completed in 2 hours with near quantitative yield. However, the conversions of polymerization reaction with increased  $R_{\text{monomer/cat}}$  values decreased to 67 and 61% for  $R_{\text{monomer/cat}} = 100$  and 200, respectively. Increasing the reaction period did not improve the conversion.

If the polymerization reaction undergoes *via* living polymerization mechanism, the number averaged molecular weight ( $M_n$ ) of the polymer is expected to be  $\sim C \times M \times R$  approxi-

**Figure 2.** The relation between  $T_g$  vs  $M_w$  of PLAs prepared by (MPMA)  $\text{ZnBn}_2$  (closed squares). The open marks and the dashed trend lines are from the previous work that describes a sharp (circles and triangles) and a shallow (open squares) dependence of  $T_g$  on the  $M_w$  of PLAs in the narrow and the broad MWD regime for the former and the latter, respectively.<sup>50</sup>

mately, where  $C$  is the conversion,  $M$  is the molecular weight of a monomer, and  $R$  is the  $[M]/[cat]$  ratio. Observed  $M_n$ s of PLAs ranged from 9800 to 23000 D for three different  $[M]/[cat]$  ratios (Table 2). Given the fact that  $M_n$ s of produced PLAs have linear relationship with those predicted theoretically and observed molecular weight distributions (MWDs) of these polymers are very narrow (1.05-1.18) indicate that the major mechanism of polymerization is likely having a living polymerization character.

We have reported the trend of glass transition temperature ( $T_g$ ) in relation with MW and MWD in the previous work.<sup>50</sup> Shortly,  $T_g$  was critically dependent on  $M_w$  within the narrow MWD regime but the dependence became significantly shallow when the MWD was broadened (Figure 2). PLAs produced in this work have very narrow MWD and  $T_g$  values of PLAs again exhibit sharp dependence on the  $M_w$  similar to our previous results.

In sum, a new approach towards the synthesis of a ring-opening polymerization catalyst for the preparation of PLA has been achieved. The air and moisture stable (MPMA)  $ZnCl_2$  complex was first prepared and its structure was determined by X-ray crystallography. Replacing two Cl ions with benzyl groups under mild condition afforded (MPMA)  $ZnBn_2$ , which are active for the PLA synthesis.

**Supplementary data.** CCDC 698373 contains the supplementary crystallographic data for (MPMA) $ZnCl_2$ . These data can be obtained free of charge via <http://www.ccdc.cam.ac.uk/conts/retrieving.html>, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: [deposit@ccdc.cam.ac.uk](mailto:deposit@ccdc.cam.ac.uk)
